**Abstract**— In this paper data mining technique available which useful in mining the pattern of text document. However efficiently Research of new pattern which is useful and update the discover patterns is still an open research issue, especially in text mining field. Existing text mining methods have term based approaches and they have problems of polysemy and synonymy. To reduce these problems people develop the phrase (pattern) based approach. The phrase based approach is better than the term based approach but many experiments are not done in phrase based approach. In this we present the new innovative and effective pattern discovery method which has a process of pattern deploying and pattern evolving, which improve the efficiency and updating new pattern for finding appropriate and interacting information.

**Keywords**-Text Mining, Pattern Mining, Pattern Evolving, Pattern Extraction

## I. Introduction

We have develop the methods of knowledge discovery and data mining because in existing years there is quick growth in digital data, so it is needful to turn this data into useful information and knowledge. The applications like market analysis and business management can have advantages; by the use of this information and knowledge extracted from a large amount of data. Knowledge discovery is the process of nontrivial extraction of information from big or large databases. Information Is unknown and actually useful for users. Therefore Data mining is an important step in process of knowledge discovery in large databases.

In a last five to ten years, to perform different knowledge tasks the data mining technique are presented. These techniques are (I) association rule mining, (II) frequent item set mining, (III) sequential pattern mining, (IV) maximum pattern mining, and (V) closed pattern mining. Mostly focus of these techniques is efficient mining algorithms used to find particular pattern which is a reasonable and acceptable in time frame. Using these techniques, number of patterns for data mining is generated. How these patterns effectively use and update is still an open research issue. But there is still scope for the research. In this paper we have focus on the development of a knowledge discovery model which effectively use and update the patterns which are discovered and apply it to text mining.

Text mining is discovery which applied to text mining in the interesting knowledge in the text documents. It is a challenging issue to find exact knowledge (or features) in text documents to help users to find what they want? Firstly, information Retrieval (IR) provided many term-based methods to solve this challenge, such as Rocchio and probabilistic models, rough set models, BM25 and support

vector machine (SVM) based filtering models. The profits of term- based methods include able computational performance as well as mature theories for term weight; they have emerged over the last twenty years from the IR and communities of machine learning. However, term- based methods suffer from the problems of synonymy and polysemy, where synonymy is multiple words having the same meaning and polysemy means a word has multiple meanings. The semantic meaning of many discovered terms is unsure for answering what users want. Over the years, people have often held the hypothesis that phrase-based approaches could perform better than the term-based ones, as phrases may carry more “semantics” like information. This hypothesis has not fared too well in the history of IR. Although phrases are less ambiguous and more discriminative than individual terms, the reasons for the discouraging performance as follow: 1) phrases have inferior statistical properties to terms, 2) they have low frequency of occasion, and 3) there are large numbers of excessive and noisy phrases among them.

In the presence of these setbacks, sequential patterns used in data mining community have turned out to be a promising alternative to phrases. Because sequential patterns enjoy good statistical properties like terms. To overcome the disadvantage of phrase-based approaches, pattern mining-based approaches is used, they adopted the concept of the closed sequential patterns and the pruned non closed patterns. These pattern mining based approaches have shown some extent improvements on the effectiveness.

There are two fundamental things regarding the effectiveness of pattern-based approach as low frequency and misinterpretation. Given a special topic, a highly frequent pattern is usually a general pattern, or a specific pattern of low frequency. If we not given the support, a lot of noisy

Corresponding Author: S.S. Patil

patterns would be searched. Misinterpretation means the measures used in pattern mining (e.g., "support" and "confidence") which is not suitable for discovered patterns to give answer what we want. The main problem hence is how to use discovered patterns to accurately evaluate the weights of useful knowledge in text documents

Over the years, IR has developed many mature techniques which demonstrated the terms were which important features in text documents. However, general terms have larger weights (e.g., the term frequency and inverse document frequency (tf\*idf) weighting scheme) because they can be frequently used in both relevant and irrelevant information. For example, term "LIB" may have larger weight than "JDK" in a certain of data collection; but we believe that term "JDK" is more specific than term "LIB" for describing "Java Programming Language". Therefore, it is not adequate for evaluating the weights of the terms based on their classifications in documents for a given topic. These new method has been frequently used in developing information retrieval models.

In order to solve the above inappropriate statement, we present an effective pattern discovery technique, which evaluates discovered peculiarity of patterns. Then evaluate term weights according to the classification of terms in the discovered patterns rather than the distribution, for solving the wrong interpretation issue. It also considers the impact of patterns from the negative training to find ambiguous (noisy) patterns and try to reduce their influence for the frequency problem. The process of updating uncertain patterns can be referred as pattern evolution. The proposed approach can improve the correctness of evaluating term weights because discovered patterns are more definite than whole documents. We also conduct numerous experiments on the latest data collected, Reuters Corpus Volume 1 (RCV1) and Text Retrieval Conference (TREC) filtrating topics, to evaluate the proposed technique. The results show that the proposed technique outperforms up-to-date data mining-based methods, the state-of-the-art term- based methods and concept-based models.

## II. RELATED WORK

The number of text representations has been developed in the past. A famous one is the bag of words that uses keywords (terms) as elements in the vector of the feature space. In, the  $tf*idf$  weighting systematic plan is used for text representation in the systematic Rocchio classifiers. With TFIDF, the universal IDF and entropy weighting plan is put forward and improves performance by an average of 30 percent. Different systematic plan for the bag of words represent technique. The problem of the bag of words technique is to select a limited number of features among an huge set of words in order to increase the system's efficiency and avoid over fitting in order to reduce the number of features, many dimensionality reduction techniques are conducted by the use of feature selection techniques, such as

Mutual Information, Information Gain, Odds ratio, Chi-Square, and so on.

The choice of a presentation depended on what is regards as the meaningful units of text and the meaningful natural language rules for the combination of these all units. With respect to the presentation of the content of documents, some research works not use individual words it uses phrases. In the combination of unigram and bigrams was selected for document indexing in Text Categorization (TC) and assess on a variety of feature evaluation functions (FEF). A phrase-based text representation was proposed for Web document management.

For text analysis the data mining techniques are used by extracting co-occurring terms as descriptive phrases from documents. However, the effectiveness of the text mining systems using phrases for text representation showed unmeaningful improvement. The reason behind that is, phrase-based method had "lower document frequency and lower consistency of assignment for terms.

Term-based ontology mining methods also provided some thoughts for text representations. For example, hierarchical clustering was used to determine synonymy and hyponymy relations in between keywords of text. Here pattern evolution technique was introduced in order to improve the fulfillment of term-based ontology mining. In data mining communities pattern mining has been extensively studied from many years. A variety of efficient algorithms such as Apriori-like algorithms, PrefixSpan , FP-tree, SPADE, SLPMiner, and GST have been put forward. For developing efficient mining algorithms for discovering patterns from a large data collection these research works are used. However, searching for useful and interesting patterns and rules was even now an open problem in the field of text mining, various text patterns are find using pattern mining techniques, such as sequential patterns, frequent item sets, multiple grams, and co-occurring terms, for building up a representation with these new types of characteristics. Nevertheless, how to effectively deal with big amount of discovered patterns is the challenging issue. For that challenging issue, closed sequential patterns have been used for text mining, which proposed that the potential for improving the performance of text mining the concept of closed patterns in text mining was useful. Pattern taxonomy model was developed and improved the effectiveness by using closed patterns in text mining.

Here the two-stage model is used to improve the performance of information filtering that is both term-based methods and pattern- based methods.

The modern computational technology that can help people to understand the meaning of text documents is Natural language processing (NLP). The NLP was struggling for dealing with uncertainties in person's languages. Recently, a new concept-based model was presented to bridge the gap

between NLP and text mining, which analyzed terms on the sentence and document levels. This model included three components. The first one analyzed the semantic structure of sentences; the second one constructed a conceptual ontological graph (COG) to describe the semantic structures; and the last one extracted top concepts based on the first two components to build characterized vectors using the standard vector space model. The advantage of the concept-based model is that it can effectively differentiate between non important terms and meaningful terms which define a sentence meaning. Compared with the above methods, the concept-based model depends upon its employed NLP techniques.

### III. PROPOSED WORK

As the existing system implemented evaluation of term support based up on their occurrence in documents, where as the proposed system is to extract the information what a user wants in the form of terms or patterns. The data set is loaded into the data base. The data set undergoes text pre-processing phase which includes tokenization, parts of speech, and word stemming and stop word removal methods. Then terms present in the data set are analyzed in order to find out which are positive documents and which are negative documents. Pattern taxonomy model, pattern deploying techniques were implemented on positive data set in next phase one after other to discover patterns. Simultaneously, negative sets undergo pattern evolving and shuffling techniques. Therefore the term supports are evaluated. Terms will be extracted from term extraction model. Time is evaluated in time evaluation module which displays how much time taken to do the above whole process.

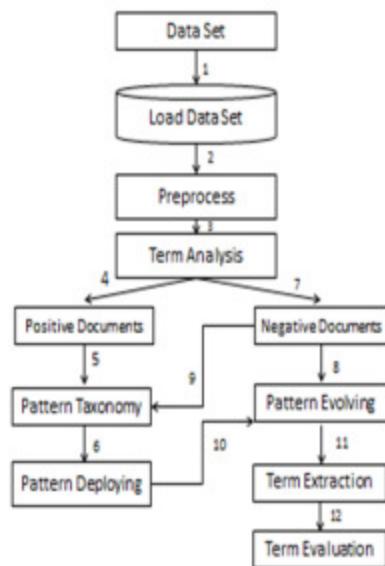

Fig1. Proposed Architecture Model Flow

#### A. Datasets

Dataset is collection of the data which present in tabular form. Here we use the data from database of big data which is the large and complex database on internet. That data is

stored in big data in SGML format. SGML is the Standard Generalized Markup Language.

### IV. SYSTEM ARCHITECTURE

The proposed architecture is shown in Figure 1. This architecture shows the stepwise solution of our project. The basic step is to load SGML documents in our database. The next step is to convert that SGML document in XML format then remove stop word and text stemming. We removed this stop word and text stemming with the help of NLP (natural language process). Fig 1: System Architecture There is 5 sub modules of proposed system.

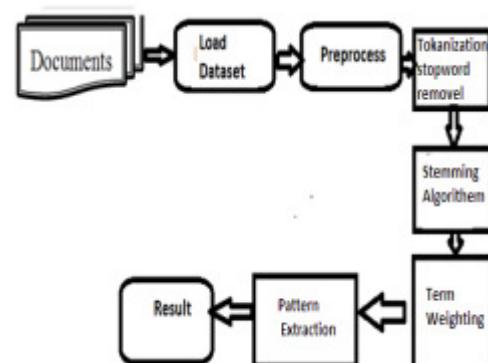

Fig 2: System Architecture

- 1) Loading documents
- 2) Text Preprocessing
- 3) Term weighting
- 4) Dimensionally Reduction
- 5) Pattern Extraction

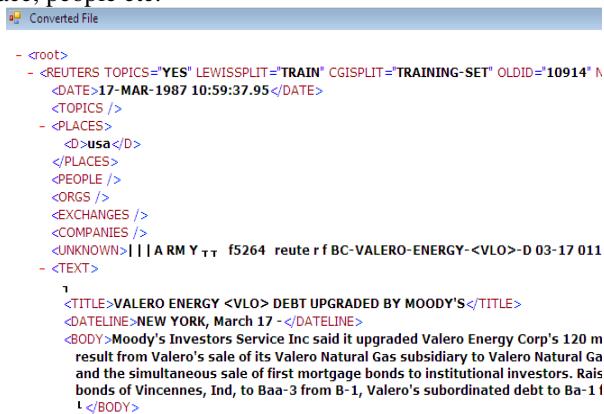

#### Loading documents

In this module, to load the SGML documents. The user retrieves one of documents. This document is given to next process that process is conversion of SGML to XML.

Fig.3 loading document

The converted document has the sub roots like topic, date, place, people etc.

## V. PRE-PROCESSING

The preprocessing phase of the study converts the original textual data in a data-mining-ready structure, where the most significant text-features that serve to differentiate between text-categories are identified, that means unstructured text documents are processed using natural language processing techniques to extract keywords labeling the items in that text documents. An effective preprocessor represents the document efficiently in terms of both space (for storing the document) and time (for processing retrieval requests) requirements and maintain good retrieval performance. The main objective of preprocessing is to obtain the key features or key terms from text documents and to enhance the relevancy between word and document and the relevancy between word and category. After this phase, classical data mining techniques are applied on the extracted data (keywords) to discover interesting patterns. Preprocessing technique contains

- Text Clean Up
- Tokenization
- Stop word removal
- Word stemming

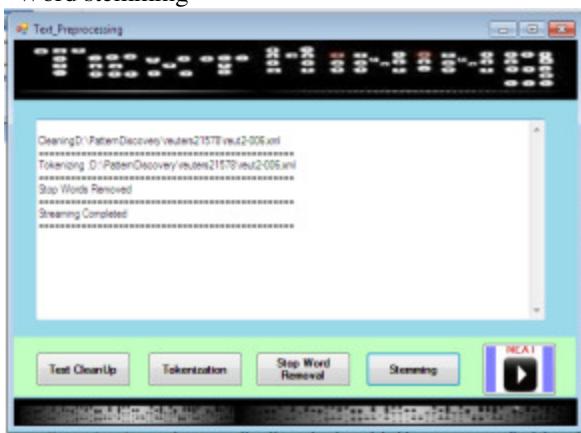

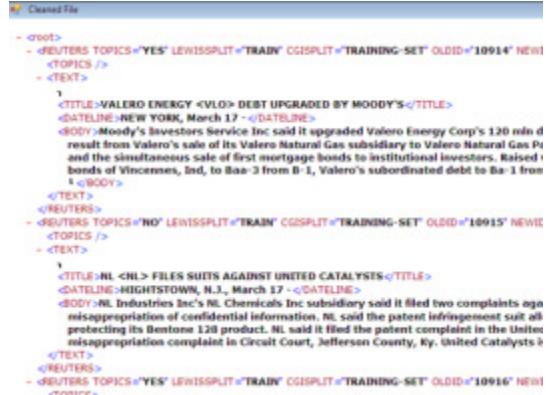

Fig.5 Pre-processing

### A. Text Clean Up

After loading the document we see the XML document has number of sub roots like date, people, org, exchange, companies etc. In text cleanup process we will remove the roots that are unnecessary like people, org, exchange, people which is not having the meaning.

### B. Tokenization

Given a character sequence and a defined document unit, tokenization is the task of chopping it up into pieces, called *tokens*, perhaps at the same time throwing away certain characters, such as punctuation. These tokens are often loosely referred to as terms or words. A *token* is an instance of a sequence of characters in some particular document that are grouped together as a useful semantic unit for processing.

### C. Stop Word Removal

Many of the most frequently used words in English are useless in Information Retrieval (IR) and text mining. These words are called 'Stop words'. Stop-words, which are language-specific functional words, are frequent words that carry no information (i.e., pronouns, prepositions, conjunctions). Stop words are needed as it reduces indexing (or data) file size, Improve efficiency and effectiveness. Some stop words are a, the, after, to, too, from, before, some etc.

  <@588></@
```

Let  $\min \sup = 50\%$ , ten frequent patterns are obtained in Table 1 using the above definitions. Table 2 illustrates the ten frequent patterns and their covering sets.

Table 2: Frequent Patterns And Covering Sets

Frequent patterns	Covering sets
$\{t_3, t_4, t_6\}$	$\{dp_2, dp_3, dp_4\}$
$\{t_3, t_4\}$	$\{dp_2, dp_3, dp_4\}$
$\{t_3, t_6\}$	$\{dp_2, dp_3, dp_4\}$
$\{t_4, t_6\}$	$\{dp_2, dp_3, dp_4\}$
$\{t_3\}$	$dp_2, dp_3, dp_4\}$
$\{t_4\}$	$\{dp_2, dp_3, dp_4\}$
$\{t_1, t_2\}$	$\{dp_1, dp_5, dp_6\}$
$\{t_1\}$	$\{dp_1, dp_5, dp_6\}$
$\{t_2\}$	$\{dp_1, dp_5, dp_6\}$
$\{t_6\}$	$\{dp_2, dp_3, dp_4, dp_5\}$

Not all frequent patterns in Table 2 are useful. For example, pattern  $\{t3, t4\}$  *always* occurs with term  $t6$  in paragraphs, i.e., the shorter pattern,  $\{t3, t4\}$ , is always a part of the larger pattern,  $\{t3, t4, t6\}$ , in all of the paragraphs. Hence, the shorter one,  $\{t3, t4\}$ , is a noise pattern and expect to keep the larger pattern,  $\{t3, t4, t6\}$ , only.

Given a termset  $X$ , its covering set ' $X$ ' is a subset of paragraphs. Similarly, given a set of paragraphs  $Y$  is a subset of  $PS(d)$ , Its termset can be defined, which satisfies  $Termset(Y) = \{tl \ dp \ Y \Rightarrow t \ dp\}$  The closure of  $X$  is defined as follows:

$$Cls(X) = termset(X).$$

A pattern  $X$  (also a termset) is called closed if and only if  $X = \text{Cls}(X)$ .

Let  $X$  be a closed pattern. We can prove that

$$Supa(X1) < supa(X),$$

For all patterns  $X$  is a subset of  $X1$ ; otherwise, if  $\text{supa}(X1) = \text{supa}(X)$ , we have  $X1 = X$ .

Where  $supa(X1)$  and  $supa(X)$  are the absolute support of pattern  $X1$  and  $X$ , respectively.

Pattern taxonomy has been evaluated to discover closed patterns. Patterns can be structured into a taxonomy by using the (or subset) relation. For the example of Table 1, where a set of paragraphs of a document are illustrated, and the discovered 10 frequent patterns in Table 2 if assuming  $min\_sup = 50\%$ . There are, however, only three closed patterns in this example. They are  $\{t3, t4, t6\}$ ,  $\{t1, t2\}$ , and  $\{t6\}$ . Fig 1 illustrates an example of the pattern taxonomy for the frequent patterns in Table 2, where the nodes represent frequent patterns and their covering sets; non-closed patterns can be pruned; the edges are “is-a” relation. After pruning, some direct “is-a” retaliations may be changed, for example, pattern  $\{t6\}$  would become a direct sub pattern of  $\{t3, t4, t6\}$  after pruning non-closed patterns. From frequent patterns and closed patterns, closed sequential patterns have been discovered using SP Mining algorithm.

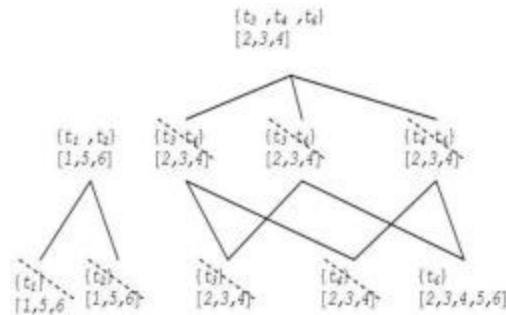

Fig. 11 Pattern Taxonomy

### A. Term-weighting

There are many ways to define the term-weighting for the nonzero entries in such a vector. For example, we can simply set  $TF(d; t) = 1$  if the term  $t$  occurs in the document  $d$ , or use the term frequency  $freq(d; t)$ , or the relative term frequency, that is, the term frequency versus the total number of occurrences of all the terms in the document. There are also other ways to normalize the term frequency. For example, the Cornell SMART system uses the following formula to compute the (normalized) term frequency:

$$TF(d, t) = \begin{cases} 0 & \text{if } freq(d, t) = 0 \\ 1 + \log(1 + \log(freq(d, t))) & \text{otherwise.} \end{cases}$$

Besides the term frequency measure, there is another important measure, called inverse document frequency (IDF), that represents the scaling factor, or the importance, of a term  $t$ . If a term  $t$  occurs in many documents, its importance will be scaled down due to its reduced discriminative power. For example, the term *database systems* may likely be less important if it occurs in many research papers in a database system conference.

According to the same Cornell SMART system,  $IDF(t)$  is defined by the following formula:

$$IDF(t) = \log \frac{1 + |d|}{|d_t|},$$

where  $d$  is the document collection, and  $dt$  is the set of documents containing term  $t$ .

### B. Dimensionally Reduction

In previous term weighting we have the weights for every term or the token. Here in dimensionally reduction we will remove the terms or tokens who have weights less than user define and which is more than 0.

### C. Pattern Extraction

The searching process undergoes in frequent patterns, closed and closed sequential patterns in order to extract the information which a user wants in form of terms. Along with terms,  $n_{ij}$  is its support in  $di$  which is the total absolute paragraph (D+ or D-) is extracted which contains supports given by closed patterns that contain  $tij$ ; or  $n_{ij}$  is total number of closed patterns that contain  $tij$ . The process of calculating d-patterns can be easily described using pattern taxonomy model algorithm. If the term what is required has found out during searching process in any of the extracted patterns, searching is aborted. Here for the support and confidence following formulas are used

$$support(X \Rightarrow Y) = P(X \cup Y).$$

$$confidence(X \Rightarrow Y) = P(Y|X).$$

Here support indicates that a transaction contains both  $X$  and  $Y$ , that is, the union of itemsets  $X$  and  $Y$  and confidence indicates conditional probability that is, the probability that a transaction containing  $X$  also contains  $Y$ .

Fig.14 Pattern Extraction

## VII. EXPERIMENTAL METHOD

In the experimental procedure, few users will be allowed to choose the particular document what they want. In search option of this application developed, users enter the required keyword of their interest, such that selected document undergoes preprocessing, terms are analyzed, frequent patterns, closed and closed sequential patterns are extracted. If the required key word is obtained in any one of extracted patterns, searching process will be aborted. All these results will be analyzed along with the feedback taken from every user to know the accuracy of process. The time taken for obtaining the optimist result will be compared with time taken for term based approach. Hence it can be proved that proposed approach is more accurate than term based approach.

## VIII. CONCLUSION

This paper is intended to extract the useful information for users what he want. The extracted information will be in form of terms. In preprocessing, the document is tokenized, word stemming is done, and stop words are removed. The terms are analyzed, which undergoes pattern taxonomy, pattern deployment, pattern evolving, and term extraction to get accurate result.
